Abstract

High-speed spray imaging is widely used in the researches of internal combustion engines, however, extracting physically-consistent, large-scale quantitative data remains challenging due to noise, occlusion and high computational cost. The thesis presents an end-to-end framework that transforms high-speed images into a reliable and data-driven visualization and analysis tool for in-cylinder fuel sprays. The framework integrates parallelized computer vision (CV) processing with physics-informed neural networks (PINNs) within a unified pipeline.

This framework allows for the effective extraction of spray parameters, data-driven training of PINNs under physical constraints, and quick inferences of two-dimensional spray shape predictions for the analysis of parametric piston surface interaction. The setup is able to perform precise reconstruction of spray evolution and collision prediction. The system functions as a practical surrogate modelling tool for investigating spray–structure interactions and is therefore well suited to rapid design iteration in engine-related applications.

The proposed method enables efficient extraction of spray geometries, physics-informed training of the PINN, and rapid, near real-time prediction and reconstruction of 2D spray boundaries. This surrogate modelling framework supports the investigation of interactions among the spray, the engine cylinder, and the parametrised piston surface.

Overall, the proposed framework serves as a practical surrogate modelling approach for spray–structure interaction analysis and supports rapid design iteration in engine-related applications.

1 Introduction

High-speed spray injection processes play a central role in influencing the performance, efficiency and durability of internal combustion engines [1]. In-cylinder fuel spray behaviour directly influences mixture formation, combustion stability, wall-wetting and the formation of pollutants. Therefore, spray imaging experiments have become an essential tool in the engine research and optimisation processes.

Despite the significant progress in the development of high-speed imaging techniques, transforming raw spray videos into quantitative, scalable and physically meaningful information remains a challenging task [3]. Noise in images, occlusion, limited optical access and the large volume of experimental data combine to form a significant challenge in traditional analysis methods. At the same time, high-fidelity numerical simulations such as computational fluid dynamics (CFD), despite being accurate, are computationally expensive and often aimed at the design verification step, being impractical for rapid prototype iterations or real-time analysis [4].

Recent developments in data-driven modelling and physics-informed machine learning (PIML) offer new opportunities to bridge experimental measurements and physical modelling [5, 2]. Particularly, by introducing governing physical constraints into the training process of the neural networks, conventional purely data-driven deep learning models become physics-informed neural networks (PINN) that explicitly incorporate physics, enabling improved generalisation from limited and noisy data. However, it remains an open challenge to practically integrate all processes of experiment-based digital image processing, physics-informed learning, and fast inference for engineering applications.

This thesis addresses this challenge by proposing an end-to-end framework that connects high-speed spray imaging, parallelised computer vision, physics-informed deep learning, and surrogate-based inference for spray–structure interaction visualisation for analysis.

1.1 Background and Related Works

Spray imaging techniques such as Mie scattering and Schlieren imaging are already widely used in the studies of penetration distances, spray cone angles and overall spray morphology in internal combustion engines. Classical image processing techniques – including manual thresholding, contour detection and motion-based analysis – are widely used for extracting geometric features from experimental spray images. For all small datasets, these methods often require extensive manual calibration on first- or second-order parameters, do not scale well to large experimental campaigns, or have limited robustness for changes in experimental setup, such as camera or background lighting

Meanwhile, numerical simulations based on CFD have become a standard tool for

predicting spray spatial and temporal evolution and spray-wall interactions. Although CFD simulations can provide the information of whole flow field, its high computational cost limits its applicability in parameter studies and iterative design workflows; for example, dense, wide-range parameter sweeps are impractical with CFD.

More recently, machine learning approaches have been explored as surrogate models for complex physical systems. Purely data-driven models offer fast inference but often lack physical consistency, especially when trained on limited or noisy data. PINNs have been introduced to address this limitation by embedding governing equations and physical constraints directly into the learning processes. Many existing studies in PINNs are trained on high-fidelity CFD data. However, their effective integration with the geometric features extracted from experimental spray images has not yet been clearly investigated.

1.2 Objectives and Research Questions

The main objective of this thesis is to develop a practical and computationally efficient framework for transforming high-speed spray imaging data under constant ambient density from Mie-scattering setups to physically consistent, engineering-relevant predictions. The work focuses on integrating existing open-source tools and established methods rather than developing new algorithms.

The main research question addressed in this thesis is therefore:

How can experimental spray imaging data captured by Mie-scattering techniques be efficiently processed and combined with physics-informed learning to enable fast and reliable prediction of spray evolution and spray-structure interactions?

To address this question, the following sub-problems are considered:

- How to design a computer vision pipeline capable of extracting spray 2D geometric parameters from high-speed imaging data that is robust to lighting shifts in experimental setups and noise from camera sensors or background?
- How to accelerate the computer vision pipeline that can handle large volumes of high-speed imaging data with the techniques from parallel programming?
- How to use the trained PINN models for fast inference to reconstruct two-dimensional spray shapes and for predicting interactions with parametric piston surfaces and cylinder walls?

2 Literature review

2.1 Mie Scattering in Optical Spray Imaging

Optical spray imaging based on Mie scattering is widely used to visualize liquid fuel sprays due to its experimental simplicity and high temporal resolution. However, the interpretation of Mie-scattering intensity fields is fundamentally limited by the nonlinear, size-dependent, and geometry-dependent nature of the scattering process. As a consequence, direct inversion from measured image intensity to physical quantities such as liquid mass, droplet number density, or local volume fraction is intrinsically ill-posed.

Instead of attempting pointwise physical reconstruction, most image-based spray analyses rely on feature-level abstractions, in which visually stable structures—such as spray boundaries, envelopes, and penetration fronts—are extracted and treated as observables for further analysis.

2.1.1 Physical Basis of Mie Scattering in Fuel Sprays

Mie scattering describes elastic light scattering by particles whose characteristic size is comparable to the incident wavelength. In typical diesel and gasoline sprays, droplet diameters span approximately 1–50 μm , while visible illumination wavelengths are on the order of 0.5–0.6 μm , placing most practical spray-imaging conditions firmly within the Mie regime.

Under these conditions, the scattering response depends strongly on droplet size, refractive index, and observation angle. The scattering cross-section exhibits oscillatory behavior with respect to the size parameter, and forward scattering becomes increasingly dominant for larger droplets. Consequently, the recorded image intensity primarily reflects size-dependent angular scattering characteristics rather than a direct or monotonic measure of liquid mass.

2.1.2 Nonlinearity with Droplet Concentration and Multiple Scattering

In addition to single-particle scattering effects, dense spray regions introduce strong nonlinearities through multiple scattering, shadowing, and saturation phenomena. At high optical depths, the assumptions underlying linear light attenuation models, such as the Beer–Lambert law, break down.

As a result, integrated pixel intensity becomes a nonlinear function of droplet number density and spatial distribution. Two spray regions containing identical liquid mass may therefore produce substantially different image intensities, depending on local droplet size distributions and optical path length.

2.1.3 Sensitivity to Optical Configuration and Illumination Geometry

The measured Mie-scattering intensity is further influenced by experimental factors, including illumination angle, collection optics, numerical aperture, and camera response. Even for physically identical sprays, variations in optical configuration can lead to markedly different intensity distributions.

This sensitivity limits the portability of absolute intensity-based metrics across experiments and reinforces the need for analysis strategies that depend on relative, structural, or contrast-based features rather than absolute intensity values.

2.1.4 Image Intensity, Visual Perception, and Segmentation Validity

Although Mie-scattering intensity does not provide a direct measure of physical spray quantities, certain visually salient features remain remarkably robust across varying conditions. Human visual perception effectively performs a contrast-based segmentation of the spray, focusing on regions of rapid intensity transition rather than absolute brightness.

Consequently, spray boundaries and envelopes—defined as regions of pronounced intensity gradients—have been widely adopted as operational observables in image-based spray analysis. While such features do not correspond to sharp physical interfaces, they offer reproducible and visually stable representations that support comparative and statistical analysis.

2.2 Characteristics of Spray Features

2.3 Empirical Spray Penetration Models

2.4 From Multi-Layer Perceptions to Physics-Informed Neural Networks

2.5 Structure of the thesis

The thesis comprises the front matter, the main matter and possible appendices. The front matter in the required order is:

- a cover page,
- a page containing copyright information,
- the abstract page(s),
- an optional preface, and
- a table of contents.

If the thesis contains mathematical equations, give the list of symbols used to represent various quantities along with the mathematical operators used. The list must contain all the abbreviations used as well. Note that lists of figures and tables are not required.

The main matter, i.e. the actual thesis, begins after the list of symbols and abbreviations. Its structure follows the standard structure used in scientific writing. A typical division of the content is

1. Introduction (research objectives and questions)
2. Literature review (research made earlier in this area)
3. Research material and methods
4. Results / Findings
5. Discussion
6. Summary / Conclusions
7. References

The parts 1–6 in the list above are the text of your thesis. Often the discussion and summary (or conclusions) are combined in one chapter. The wording of the titles suggested above may differ. As a matter of fact, the titles above refer more to the type of content rather than being title suggestions. For example, the literature review of a thesis on electromagnetics could be under the title ‘Electromagnetic theory and FDTD’. The background to the methodology used—FDTD here—could also be in this chapter. Note that the chapters and sections within the main matter are numbered, and that they appear in the table of contents. The references, or the bibliography, is also shown in the table of contents, but without a number labelling it.

The appendix or appendices, when necessary, are presented in the last part of the thesis. They contain things like questionnaires used in the study, [selected parts of] data, derivations of mathematical results, a more detailed exposition of some aspect in the thesis, or code listings. Number them in the table of contents as follows:

- A. The first appendix
- B. The second appendix

Refer to a suitable guide on writing a thesis for a comprehensive description; there are plenty of them around. The instructions here are not exhaustive, and they concentrate more on how to use this template.

A bachelor’s thesis is ideally about 20 pages long, excluding the appendices, whereas a master’s thesis is about 60 pages long, again, not counting the pages in the appendices. The numbers pertaining to the length of your thesis given here are mere rules of thumb. Consult your school’s thesis guidelines and your thesis advisor and/or supervisor for the appropriate length in your case.

2.6 Page numbering

Number the pages using Arabic numerals, placed in the centre of the page footer. The numbering begins from the cover page and runs continuously to the end of the thesis. Enter the total number of pages in the thesis—front matter, main matter and appendices, if present—in the appropriate field on the abstract page. Enter also the number of pages in the appendices, if present, in the same field on the abstract page as follows: total number of thesis pages / number of pages in the appendices.

Do not print the page numbers on the cover and the copyright pages; number all the other pages. Thus, the first page with a page number printed on it—the first abstract page—is ‘3’. The page numbering of appendices continues from that on the previous page.

2.7 Structuring the text in the main matter

2.7.1 Sections

You can structure your text by dividing it into sections with a suitable title. Well-devised sectioning clarifies your text, but beware of overusing them, since that will fragment and confuse your text. Do not use more than three levels of hierarchy in your sections. Notice that the section titles, just as the figure and table labels, are in a Helvetica clone, a sans serif, or grotesque, font. The main matter text is typeset in a Times clone, a serif font.

The sectioning macros available in $\text{\LaTeX}$ are

```
\section{title},  
\subsection{subtitle}, and  
\subsubsection{subsubtitle}.
```

The formatting specifications are in appendix B. The fonts specified there are for Word documents, as specified by Aalto’s visual guidelines. No corresponding fonts are officially specified for $\text{\LaTeX}$. Hence, similar corresponding fonts provided by the `newtxtext` package are used in this template. Math fonts are those from `newtxmath`. The most important factor that influenced this choice of fonts was that the package outputs PDF/A-1b compliant pdf using `pdflatex`.

At least in technical texts, refraining from using the articles ‘a’ and ‘the’ as the first word in the title is common practice. Appendices are enumerated using capital letters. Begin every section on a new page. Begin a subsection on a new page only if the previous page is full. Similarly, begin every appendix on a new page.

2.7.2 Paragraphs

The paragraph that follows the section title is not indented, the paragraphs that follow are. Often, the body text is typeset as `raggedright` to avoid unnecessarily large white spaces between words. On the other hand, in many technical fields, the text is justified on both sides, but in such cases, hyphenation is used to maintain reasonable separation

between words. This template uses justified text with automatic hyphenation. Write paragraphs so that they span more than three lines. Rethink your text, if you end up having one-line paragraphs; avoid them in your thesis—including the appendices. In addition, you may need to reconstruct your text if your paragraphs are too long. Avoid emphasising text using italics. Italicised text makes reading for dyslexic readers even more difficult.

When a number has a unit associated with it, ensure two things: the space between the number and the unit is smaller than the regular space (for example, 1 Hz) and the number and unit are not split over lines. You can simply use `\,` between the number and the unit without spaces between them to stop them from being split (`1\,Hz`) or use the package `siunitx`.

2.7.3 Equations

Equations are numbered using Arabic numerals, typically enclosed in parentheses, but not always. This template encloses equation numbers in parentheses. An example equation is

$$f(x) = a_0 + \sum_{n=1}^{\infty} \left(a_n \cos \frac{n\pi x}{L} + b_n \sin \frac{n\pi x}{L} \right). \quad (1)$$

Closely related equations like equations in a system of equations may be numbered as follows:

$$V_s = R_s i_s + R(i_s + i_b) \quad (2a)$$

$$V_b = R_b i_b + R(i_b + i_s). \quad (2b)$$

All equations need not be numbered. Remember punctuation after the equation; an equation is an integral part of your sentence and may need to be followed by punctuation marks. Many scientific journals do not use them after equations; then again, many do. Punctuate the equations in your thesis. Numbering of equations in appendices consists of the appendix numbering alphabet followed by the equation number, which starts from one in each appendix. For example, the first equation in appendix A would be equation (A1) and the first two equations (A1)–(A2).

2.7.4 Figures and tables

Theses generally contain figures and tables, which have captions describing them. For figures, the convention is to place the caption after (below) the figure, as shown in figure 1 and figure 2. Tables, on the other hand, have the caption above (before), as evident from table 1. The label and number are typeset in the sans serif bold 12-pt typeface and the caption in the serif 12-pt normal typeface (see appendix B).

Avoid placing figures and tables such that they are preceded or followed by just a line or two, because the reader can have difficulties in finding the line(s) of text and might even accidentally miss the text completely. Consider, for example, a page beginning with one line of text continued from the preceding page and that ends the paragraph. This is followed by a figure, then a short three-line paragraph, then yet

Figure 1: A coil terminated in two LEDs with a magnet placed at its centre!!

Figure 2: Example of a MATLAB graph.

another figure, followed by more text, which is positioned such that only two lines of text are on the page and the remainder is placed on the following page. The layout of this page is fragmented, and as a result, the reader might initially miss the top line of text. Consider using one of the following three layout possibilities: place the figures in the top part of the page followed by the text, or place the text in the top followed by the figures, or place all the text in the middle with one figure on the top and the other at the bottom. Base your choice on considering how easily the reader can follow your text (the content of the figures affects this), and whether the page as a whole looks ordered and pleasing to the eye.

Strive to place the referenced figure or table on the same page as where it is referenced. If this is difficult, place it on the following page, but not very much further. Using the options b (for bottom), t (for top), h (for here) and p (for separate page)

Table 1: An example table. Common animals classified into their classes.

Mammals	Birds	Insects
dog	crow	ladybird
cat	sparrow	ant
rat	tit	cockroach

judiciously in the `figure` and `table` environments, $\text{\LaTeX}$ does a pretty good job of placing figures and tables. However, placing figures (and tables) close to where they are referred to may be impossible when you have many pictures, so use common sense and keep the reader in mind when placing pictures and tables.

2.8 Referencing parts in the thesis

Cross-referencing in $\text{\LaTeX}$ is simple and straightforward: use `\label{marker}` to label the object with a number and then refer to the object using `\ref{marker}`. `marker` should be a unique string of characters. To help keep you organised with the various reference labels, be systematic when creating them for different objects in the thesis. For example, start labels for figures with `fig:`, for tables with `tab:`, `sec:` for sections, and `eq:` for equations, as done in this template. So, you could have, say, `\label{sec:ohmslaw}`, `\label{eq:ohmslaw}`, `\label{fig:ohmslaw}`, and `\label{tab:ohmslaw}`.

Perhaps you will have noticed that when referencing objects in the text, as is done for ‘figure’ earlier in the text, the label ‘figure’ in the cross-reference is not capitalised. Often, you see the capitalised label ‘Figure’. In such cases, the label together with the number, for example ‘Figure 2’, is considered a proper noun, hence the capitalisation. Although this template uses the lowercase form, you can choose how you write cross-referencing labels: ‘figure’ or ‘Figure’—you will do well to consult your advisor and supervisor about this; they may have strong opinions on the matter. However you decide to write cross-referencing labels—figure, table, section or equation—be consistent.

Do not abbreviate any of the labels, for example ‘figure’ to ‘fig.’ or ‘Fig.’. Journals do this because the amount of available space for an article is limited; space is not an issue in your thesis. You can refer to more than one figure, for example, by saying figures 1 and 2. Use endash ‘--’ to specify a range: sections 1–5.

To reference a section, place the section label directly after the sectioning command of the section to be referenced. For example:

```
\subsection{Ohm's law}
\label{sec:ohmslaw}
...
...as discussed in section~\ref{sec:ohmslaw}, the resistance...
```

The tilde placed between ‘section’ and ‘`\ref{sec:ohmslaw}`’ not only puts a normal space between the two, but also binds them so that they are not split over separate lines if the two occur at the end of a line. Put a tilde between all labels and the reference number.

For figures and tables, place the label text after `\caption`. For simple equations, the label is placed after `\begin{equation}`. You can reference individual items such as equation (2a) in a grouped equation environment like `subequations` or an item in an itemised list like item 1 on page 12 or the system of equations (2) by putting a `\label` appropriately.

2.9 Citation

The list of reference must be carefully made, following one of many different styles. Which you choose depends on the field of your thesis. However, citing using footnotes is not allowed in your thesis¹. A short reference list can have entries in the order in which they are cited, but if your list is long, arrange the entries in alphabetical order. Read appendix C for a fairly thorough discussion of how to cite work in academic writing and make a bibliography or list of references. Remember that referencing is a very important part of your thesis, so be meticulous and thorough.

2.9.1 Bibliography or list of references

Find here a list of some of the typical entries in the bibliography and the information they must contain. For a more comprehensive list, see [aaltolib]. See appendix C for details on how this information must be typeset in different reference styles.

A book entry must contain the following:

- author(s)
- title of the book
- edition, if there are more than one
- publisher
- place of publication
- time of publication (typically year)
- name of series, if the book is part of a series

References [**Kauranen**]**–**[**Koblitz**] are examples of books in the bibliography. Referring to a particular place in a book, for example like this, [**Koblitz**], is a good practice. The reader can thus find the referred matter easily.

The following must be found in an article entry:

- author(s)
- title of the article
- name of the journal or magazine where the article is published
- volume number of the journal or magazine
- issue number of the journal or magazine
- year of publication
- page numbers of the published article

References [**bcs**]**–**[**Deschamps**] are examples of articles in a bibliography.

An edited book or compilation of contributions, typically chapters or articles, from several authors having one or more editors or a compiled conference proceedings must have the following information:

¹ Adding comments in footnotes is not allowed either.

- author(s) of the chapter or part
- title of the chapter or part
- mention the kind of publication ‘In book’, or for conference proceedings with no editor information use ‘In’ before the name of the conference proceedings
- editor(s) of the compilation identified with (Ed.) or (Eds.)
- name of the compiled book or conference
- for a conference article, the time and place where the conference was held
- edition, if more than one
- place of publication
- publisher (may not exist for conference proceedings)
- time (year) of publication
- pages of cited contribution
- name of series, if the book is part of one

References [**Sihvola**]-[**Lindblom**] are examples of references to a part of a compilation.

Theses must have the following information:

- author
- title of the thesis
- type of thesis (bachelor’s, master’s doctoral, other)
- name of university or institution
- name of the department, faculty or degree programme
- location/place of the university or institution
- year of publication

References [**Miinusmaa**]-[**Lonnqvist**] are examples of theses in a bibliography.

Standards must have the following:

- standard identifier and number
- name of the standard
- edition, if not the first
- place of publication
- publisher
- year of publication
- number of pages

Reference [**sfs**] is an example of how a standard is entered in a bibliography.

An interview entry must have the following details:

- name of the interviewee
- position or t academic and/or professional title

- organisation where the interviewee is placed
- address of the organisation
- a mention that the entry is an interview along with the date of the interview

Reference [**interview**] is an example of an interview entry in a bibliography.

Most scientific articles are available online nowadays and many also in printed form. Articles from journals, magazines or other publications available only online must have the following details in the bibliography:

- author(s)
- name of the article
- name of the publication (journal or magazine)
- type of publication
- edition or volume
- volume number and issue details of publication and article
- year of publication along with details on possible updates: Updated, date of update
- mention ‘Accessed’ and date when accessed
- mention ‘Available’ and URL or mention ‘DOI’ ja DOI number (DOI=Digital Object Identifier).

References [**Ribeiro**]**–[kone]** are examples of how theses available online are presented in a reference list. Additionally, references [**Ribeiro**] and [**Stieber**] available both online as well as in print, so the details are presented as for the corresponding entry in print and the details of the online version are also given. Reference [**kone**] is available only online, so only those relevant required details are given. Unfortunately, the details on the edition, publication name and number are often unavailable and so cannot be presented in the reference list.

For a thesis that is only available online, give the following details:

- author
- thesis title
- type of medium (online, DVD, CD-ROM etc.)
- type of thesis (bachelor’s, master’s doctoral, other)
- name of institution or university
- name of the department, faculty or degree programme
- location/place of the university or institution
- year of publication
- date of citation
- availability: mention ‘Available’ and give the URL and/or mention ‘DOI’ and the DOI number

Reference [**Adida**] is an example of how a thesis available in electronic form is entered in a bibliography.

Reference [**webpage**] is an example of an online stand-alone article, one not associated with any journal or magazine. Such an article is considered a work of its own. The details required of such a stand-alone webpage are:

- author(s)
- title
- mention ‘Updated’ and date of update
- mention ‘Accessed’ and date of access
- mention ‘Available’ and the URL

If the article spans more than one page, the reference list must contain the URL of the page pointing to the entire article, typically its homepage, unless the intention is to cite a particular page in the article.

3 Research material and methods

3.1 Image Pre-Processing

3.1.1 Convolutional Filters

In Mie scattering, the pixel intensity does not correspond to clear physical boundaries of the spray plume, but is also affected by:

- Droplet diameter distribution
- Multiple scattering
- Incident light and camera response
- Speckle / shot noise

and many other factors. Therefore, in this thesis, results produced by two-dimensional convolutional filters are not treated as physical segmentations, but as an estimation to local gradient of intensity, to construct the intermediate representation of an segmentation algorithm that is stable to both the human eye and later on algorithms in the image processing pipeline.

High-Pass Convolution Kernels: Sobel and Laplacian Sobel filters represent the first-order gradient, which is sensitive at the area that human eyes "think" as the visual boundaries, or edges. It can be understood intuitively as

-
-
-

-“” segmentation mask

3.1.2 Bilateral Filter

3.1.3 Angular Occupancy Analysis

3.1.4 Efficient Image Rotation

3.1.5 Masking

3.2 Image Post-Processing and Feature Extraction

3.2.1 Time-Distance Intensity Heat-map

3.2.2 Triangular Binarization

3.2.3 Spray Tip Penetration

3.2.4 Spray Cone Angle

3.2.5 Other Spray Features

3.3 Physics-Informed Neural Network

3.3.1 Data Pre-Processing

Empirical Formulae

Synthetic Data by Extrapolations

3.3.2 Model Architecture

Multi-Layer Perceptron

Physics in Loss Function

Built-in Uncertainty Awareness

3.3.3 Training Processes

Warm Start

3.3.4 Prediction for Other Spray Parameters

3.3.5 Spray Reconstruction and Visualization from Predictions

3.3.6 Collision Detection

4 Results

Present the results of your study here and answer the research questions, asked earlier in the thesis (in the introduction, perhaps), this study strives to answer. The scientific value of your work is measured by the results you obtain along with the arguments you give to back the answers to your research questions.

Be critical of the significance of your results. You may critically scrutinise the results and your interpretation of the results here, or you may do so later in the chapter with the discussion of your work or in the conclusions part.

This part should discuss how reliable the data used in the study are. You may discuss the reliability of the conclusions drawn from the study either in this chapter or later in the discussions part. You may have the discussion in a chapter of its own, separate from the summary or conclusions.

5 Summary/Conclusions

This is where you tie up any loose ends. Tell your reader briefly and clearly what you have done, what you have discovered, and the value of your discovery in the context of similar work done earlier. Draw clear conclusions regarding the research problem, sub-problems or hypotheses. You also discuss future lines of study and new questions your study might have posed.

As the author of the thesis, you alone are responsible for ensuring that the layout, form and structure of your thesis adheres to the guidelines outlined by your school. This template aims to help you meet these requirements.

A Contents of an appendix

Appendices are not essential in a thesis, and so you must plan the content of your thesis as if it does not contain an appendix. The appendix cannot be used as a dumping ground for text and ideas from an overgrown thesis.

An appendix is an independent entity, even though it complements the thesis. So, the appendix is not, say, just a list or image or table, but contains explanatory text as well that indicates the purpose of its content. It can contain code listings, like the one below for a simplified list of commands to create an appendix.

```
\clearpage
\appendix
\addcontentsline{toc}{section}{Contents of an appendix}
\thispagestyle{empty}
\section*{Contents of an appendix}
...
text
```

Equation numbering in the appendix forms a separate, complete entity. Here are a couple of examples how equations in an appendix are numbered:

$$(x + a)^n = \sum_{k=0}^n \binom{n}{k} x^k a^{n-k}, \quad (\text{A1})$$

$$\sin \alpha \pm \sin \beta = 2 \sin \left(\frac{\alpha \pm \beta}{2} \right) \sin \left(\frac{\alpha \mp \beta}{2} \right). \quad (\text{A2})$$

The appendix can contain figures that do not fit in to complement the text in the thesis. The numbering of figures is like that of equations: see figure A1.

The numbering of tables is like that for equations and figures, as is evident from the caption of table A1.

Table A1: Caption for the table.

9.00–9.55	Safety instructions on the use of laboratories
9.55–10.00	Transfer to the laboratory

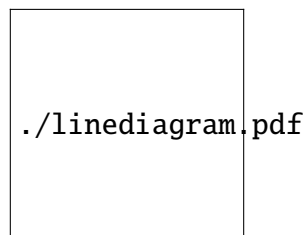

Figure A1: Figure and caption to show the numbering in the appendix.

B Page layout and typographical design

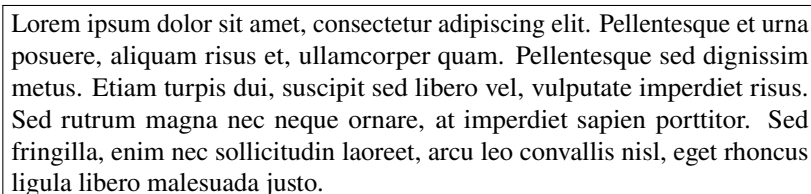

Layout choices

Designing a visually pleasing, balanced and easily readable document requires setting several typographic parameters, one of the most important ones being the line length. If too wide, the reader's eyes have trouble focusing on the text because the line length makes it difficult to gauge when the line begins and where it ends; too narrow, and the reader's eyes have to travel back too often, breaking their reading rhythm and often causing them to begin the next line before finishing the current one.

Traditional research on the effect of line length on readability of printed text have found that 45–75 characters per line (cpl) is an acceptable range, with 66 cpl being the ideal [Bringhurst, Wikilinelength]. This number includes letters, numbers and spaces. The line length in conventional books tends to be 30 times the type size, but anything between 20 and 40 times is considered acceptable. For example, for a 10-pt font, an acceptable line length is 300 points (30×10), or about 10,58 cm. The reader's experience as a reader also affects the preferred line length; an experienced reader can handle between 45 and 80 cpl for a comfortable reading experience, whereas a novice prefers a line length of between 34 and 600 cpl [Unna].

Reading text from a screen poses challenges absent in paper: glare, flicker and scrolling. Research seems to indicate that longer lines are better for scanning through the text whereas shorter lines are preferred for accurate reading. One study says that reading speed at a certain level of comprehension seems to be better for longer lines (100 cpl) than for shorter lines (25 cpl) [Dyson]. Another study [Shaik] indicates that subjective preferences for longer or shorter line lengths appear to be contradictory. About 60% of the test subjects preferred the presented shortest (35 cpl) or longest (95 cpl) lines, and at the same time all of them disliked either the shortest or the longest lines. (See also [Wikilinelength].)

Another important typographical parameter is line leading or leading, which refers to the distance between adjacent lines of text. Double spacing is a practice from the era of typewriters particularly in academia to allow making handwritten comments in documents. Typewriters had a limited number of options for leading, and double spacing was chosen as a norm. Too much leading can cause continuity problems, since the reader's eyes must travel a greater distance between lines of text. The amount of leading is a compromise between ease of reading, desired efficiency in the use of

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Pellentesque et urna posuere, aliquam risus et, ullamcorper quam. Pellentesque sed dignissim metus. Etiam turpis dui, suscipit sed libero vel, vulputate imperdiet risus. Sed rutrum magna nec neque ornare, at imperdiet sapien porttitor. Sed fringilla, enim nec sollicitudin laoreet, arcu leo convallis nisl, eget rhoncus ligula libero malesuada justo.

Figure B1: Text typeset in a 300-pt-wide box using a font size of 10 pt. The resulting average number of characters per line is about 60. The text is framed to make the box size evident.

vertical space, weight and type (serif or sans serif) of the typeface used, and visual aesthetics. Naturally, whether a document is printed or published online affects the leading, but even the language of the text must be considered when deciding on the required leading. (See also [enwiki:1026690618].)

Aalto University's visual guideline for writing documents

Of Aalto University's visual guidelines [aaltovisual], the one that applies to document writing is related to the use of fonts. This guideline specifies that the body of the text be in the serif font Sentinel and the section titles in boldface of the sans serif font Nimbus Sans. These fonts should be available on all Aalto computers. However, being a commercial product, Sentinel can be replaced with Georgia and Nimbus Sans with Arial, both of which come installed in all Windows machines. Thus, Georgia and Arial are the fonts used in the Word template. The font choices for this L^AT_EX template are a Times and Helvetica clone from the newttext package since it provides support for math fonts and its output is a PDF/A compliant pdf.

Layout and typographical specifications

Page layout in the thesis

The thesis is typeset on A4-sized paper. The text width is set to an average of about 75 cpl as a compromise between having to read the thesis on a computer screen and on paper, as discussed above. For the font size of 12 pt to be used in the body text, the text width works out to 14,2 cm. For the online version of the document, the text column is centred, implying that the left and right margins are both 3,4 cm. If you want to print the document and bind it, the binding margin must be 4,8 cm. The text height is set to 23 cm by setting the top margin to 3,7 cm and the bottom margin to 3 cm. The layout dimensions are summarised in table B1.

Table B1: Page layout dimensions.

Paper size	A4
Text width	14,2 cm
Top margin	3,7 cm
Bottom margin	3,0 cm
Online document	
Left margin	3,4 cm
Right margin	3,4 cm
Printed document (for binding)	
Left margin	4,8 cm
Right margin	2,0 cm

Sectioning and text body

The font for the body text is a 12-pt serif Times clone and a Helvetica bold clone for the section titles. Use at most three levels of hierarchy in your text: section, subsection and subsubsection. The lower section numbering must use the section number of the higher section. For example, section number 2.1.3 refers to section 2, subsection 1 and subsubsection 3.

C Reference and in-text citation guidelines

With regard to standard practice across academic disciplines, it is important to use an in-text citation to indicate when your work borrows or refers to words or ideas from a specific source. A full reference of this source should be included in your 'References' / 'Bibliography' / 'Works Cited' section as well.

There are two major referencing styles: the Harvard style and the Vancouver style. The former was first introduced in a journal article by Professor of Zoology Edward Marks in 1881 during his tenure at Harvard University (Chernin, 1988, 1062). It has since become an umbrella term to refer to styles which utilise author-date (e.g., APA style) or author-page (e.g., MLA style) within parentheses (). It still remains in use to some degree in the natural sciences (e.g., American Chemical Society, 2006) and has become the predominant style within the social sciences (e.g., American Psychological Association, 2010), and the arts and humanities (e.g., Modern Languages Association, 2016; University of Chicago Press, 2017). In contrast, the latter Vancouver style has become a very common style within the fields of engineering, technology and science. The name is derived from the inaugural meeting in Vancouver, Canada in 1978 of a committee later referred to as the International Committee of Medical Journal Editors (ICMJE) (BMA, 2012). The style is typified by its use of numbers for in-text citations; as such, it is also known as the author-number system. One of the most common versions of the Vancouver Style is the IEEE Reference Guide (IEEE 2018). The numbers used for in-text citations correspond to a numbered reference list at the end of the text. Typically, the numbers refer to the order in which the referenced authors first appear in the text. Thereafter, they continue to be referred to by this number. A lesser utilised variation of this style can feature the numbers corresponding to an alphabetical list of authors.

There is a third system of notes and bibliography. This is one of the two styles in the Chicago Manual of Style; the other is an author-date style. Notes and bibliography is mostly used by the fields of literature and history. It is occasionally utilised in the field of arts, but it is considerably less common than the Harvard style. Among the 97 English doctoral dissertations available online in AaltoDoc as of 5 March 2020, only 14 utilised this method. As it is relatively rare within Aalto University, it is recommended to visit the Chicago Manual of Style online for the reference style guide for it.

The two key considerations in adopting a particular style are that you agree with your supervisor on the particular style at the start of your thesis writing process and that you remain consistent in the use of the style throughout your thesis. Your supervisor can provide recommendations for you on the common style guides generally used in your field.

Below, you will find general guidelines to these two major styles with reference to the specific style guides in use. Corresponding examples are provided in the boxes below. Please note that the use of boxes here is only to visually separate the examples for clarity's sake and that boxes should not be used when quoting or paraphrasing in your own thesis.

Direct quotes

If you are using the exact wording from a source, you should place this in double quotation marks (“ ”) followed by the author, date, and page number in parentheses (if using the Harvard style) or a number in square brackets [if using the Vancouver style]. The citation should be on the same line and inside the punctuation. This citation should correspond to a full reference in the References / Bibliography / Works Cited section of your thesis. The punctuation used between the author, date, and page number may vary depending on which style guide you are using (compare, for example, The Chicago Manual of Style (University of Chicago Press, 2017), The Publication Manual of the American Psychological Association (APA, 2018), The MLA Handbook (MLA, 2016) and The New Oxford Style Manual (OUP, 2016)). However, it should be noted that the frequency of direct quote usage varies significantly between academic fields. While it is a fairly common practice to utilise quotes within art, design, architecture and business, it is rare in the science and engineering fields. Therefore, it is recommended that you ask your supervisor or check well-known journals in your field to gauge the frequency of quoting preferred by experts in your field.

Quoting in Harvard style

Example 1: Quote, information-prominent, American Sociological Association (2019) style

Attending to these breakdowns not only result in an on-going re-constitution of relations between people and things but are also hotbeds for unleashing everyday “creativity, invention, imagination, and artfulness” (Jackson, 2014: 226).

Block quoting

Block quotes are used for longer quotes. Note the line indentation on each line of the block quote below, starting from “There was . . .”, and the absence of quotation marks. Each style guide recommends its own minimum text length before using block quoting. [Compare: AMA - four lines of text or more; APA - 40 words or more; or Chicago - 100 words or more.]

Example 3: Block quote, Harvard style, as recommended by journal

When the Center for Bits and Atoms won the National Science Foundation Grant in 2003, MIT engineers began to look for local communities around the world they could help via digital fabrication: “Instead of bringing information technology to the masses, the fab labs bring information technology development to the masses,” explained Gershenfeld, in the official press release (NSF 2004). Karlsen had a more colourful version:

There was an innovation competition launched by MIT globally to develop local projects. MIT sent some of its best teachers to Norway to find a suitable cooperation project. They found us through Telenor, who told them: ‘There is this crazy guy lost in the fjord who devised sensors for his animals.’ We enjoyed a great year of cooperation with MIT in 2001 and we were invited to Boston to present and develop this project.

Paraphrasing

Paraphrasing is a more prevalent citation practice in many academic fields. In engineering and science, paraphrasing tends to dominate with quotations used only sparingly. In other fields, such as art and design, the ratio of quoting to paraphrasing varies significantly. Again, it is best to ask your supervisor or review journals from your field to see how common the practice is amongst your academic peers.

The intent behind paraphrasing is that you write the ideas or arguments of a source in your own words. This citation practice can allow for better integration of ideas, argumentation, and flow within the text. A good rule of thumb for paraphrasing is to have more than 80% of the paraphrased text in your own words. If you only change a few words from the original, you can run the risk of plagiarism, even if you cite the source. Words matter. If you use the exact combination of words from another author, these must be in quotes.

Paraphrasing in Harvard style

Example 4: Paraphrase, author prominent, Chicago Manual of Style (2017) style

von Hippel (1986) suggested a four-step process for working with lead users: first identifying important trends and key customer needs, then identifying lead users and understanding their needs and possible solutions and finally working with lead users in order to improve or generate product/service concepts.

Example 5: Paraphrase, information-prominent, Harvard style as recommended by journal

Obviously digital technologies will not destroy comics as we know them, but they may change their underlying decorum. In reality, these changes have continuously shaped the lives of the industry's amateurs and semi-professionals, who have to organize their time around a bricolage of fragmented schedules and poorly paid work (Woo 2015): from daily feeding a Patreon account while filling a scanlation request, to selling a print in Deviantart while reviewing the latest Doujinshi on a not-so-free-of-ads-blog are some of the patchwork tasks of the comics networked precariat in the age of semio-capitalism.

Source: Manouach, I. (2019). See <http://creativecommons.org/licenses/by/4.0/>.*

Paraphrasing in Vancouver style

Example 6: Paraphrase, information prominent, IEEE (2018) style

When a laser beam is scattered by a dielectric microparticle, resulting in light refraction on entering and leaving the particle, a small amount of momentum is transferred from the photons to the matter. This change in momentum, known as the gradient force, results in the attraction of the particle to the high intensity part of the beam (usually the centre). Optical trapping of microscale particles via this mechanism was first reported in the 1970s [1] and duly led to the initial observation of a single beam optical trap in 1986 [2]. These preliminary experiments, and many of the methodologies that developed from them, utilized the gradient force

exerted by a single, tightly focused Gaussian laser beam to trap particles in solution through what has become known as the “optical tweezer” effect. Since these initial findings, optical technology has evolved significantly, and traps that facilitate three dimensional manipulation of particles are now readily available. While originally limited to the controlled manipulation of individual particles, multitrap setups involving either splitting [3,4] or time sharing [5,6] with a single laser beam are now also commonly utilized. As a more advanced form of the former, holographic optical tweezers that employ diffractive optical elements such as spatial light modulators now allow computer controlled, independent manipulation of multiple particles [7–9]. A number of multitrap devices have also been developed based on the application of laser beams with more complex phase and intensity profiles, as for example Bessel or higher order Laguerre Gaussian beams [10–12].

Source: “Chirality in Optical Trapping and Optical Binding” by David S. Bradshaw, Kayn A. Forbes, Jamie M. Leeder, and David L. Andrews in *Photonics* 2015, available under a Creative Commons Attribution License (<https://creativecommons.org/licenses/by/4.0/>) at <https://doi.org/10.3390/photonics2020483>.

If you would like to emphasise the inventor, you could rephrase the first in-text citation as “was first reported by Ashkin in 1970 [1]” or “was first reported by Ashkin [1]” if the year is less important. (Ashkin is the sole author of the paper. It was published in 1970.)

Tips for paraphrasing

1. Identify the important points from the source text. Then, try to identify the relationship between these different parts. Is the relationship sequential, causal, contrasting, or conditional? Can these be replaced by synonyms? For example, the contrasting conjunction, but, can be replaced by however, although, nevertheless, yet or on the other hand. In many cases, these synonyms may require that you change the structure of the sentence, which in turn may help you to formulate the ideas in your own words.
2. Synonyms - A word such as give can be replaced with provide, supply or contribute. Refer to a thesaurus for more examples. You can find these online or at the Learning Centre. If you are unsure of how a new word might be used, check a dictionary or search the word in Google Scholar for examples of its use in context.
3. Common phrases - There are often multiple ways of expressing a given phrase in academic writing. For example, compare “Previous studies have not dealt with...” with “Researchers have not treated X in much detail” or “Most studies in the field of X have only focused on...” These examples were drawn from the University of Manchester’s (2018) Academic Phrasebank

(<http://www.phrasebank.manchester.ac.uk/>). This corpus of common phrases includes hundreds of examples, categorised according to their functions.

4. Additions or deletions - Can you add a missing item? Can you leave something out?
5. Change the structure of the sentence - There are many ways to change the structure. Can you change the sentence from passive voice to active voice, or vice versa? Can you rewrite the sentence with “It is” or “There is”? Can you switch to the inanimate agent, e.g. “This thesis discovered”? Refer to the Aalto University Language Centre site (<http://sana.aalto.fi/awe/>) in the “Cohesion” section for more ways to change the structure of a sentence.

Example 7: Before and After Paraphrase

Before Paraphrase

“Significant progress has been made in the use of smart textiles in wearable technology, especially in the sport and well-being sector. However, the medical sector still lacks commercial and viable solutions” (Ilen et al., 2019, p. 2).

After Paraphrase

While some industries have taken advantage of smart textiles in wearable technology, Ilen et al. (2019, p. 2) contend that the medical industry has yet to produce any viable products.

Source: Ilen, E., Groth, G., Ahola, M., & Niinimäki, K. (2019). *Empathy in a Technology Driven Design Process: Designing for Users without a Voice of their Own*. Paper presented at 8th biannual Nordic Design Research Conference: Nordes 2019: Who Cares?, Espoo, Finland. Open Access paper.

Avoiding the pitfalls of the Finnish paragraph-length paraphrase (FPP)

In Finland, there exists a method of citation that is not permitted or recognised by many international style guides, including IEEE Reference Guide (IEEE 2018); Information and documentation — Guidelines for bibliographic references and citations to information resources (ISO 690:2010(E)) (ISO 2010); New Oxford Style Manual (OUP 2012); Scientific Style and Format: The CSE Manual for Authors, Editors, and Publishers (CSE 2012); The Chicago Manual of Style (University of Chicago Press 2017); The Publication Manual of the APA (APA 2018). Due to this and the reasons discussed below, it is not recommended that this method be used when writing in English. Interestingly, the Finnish Standards Association (Suomen Standardisoimisliitto SFS ry) which emulates the ISO standard, does not recognise this either (FSA 2010). In the Finnish style of citation, writers can write an entire paragraph where every sentence comes from a single source. Then, at the bottom of the paragraph, they provide a citation in brackets outside the final punctuation (see example below). Generally, the Finnish method suggests that by putting the citation after the period, the citation then refers to all the sentences preceding it in the paragraph.

Example 8: Paraphrase, Finnish style, not recommended in English

Additive manufacturing was originally developed to guide product design by providing a way to create prototypes directly from digital designs. This method called rapid prototyping (RP), as the name implies, consumes less time and resources than most preceding techniques. For instance, the manufacturing of an injection mold for prototyping purposes would be extremely expensive. However, the part can be created with additive manufacturing for a fraction of the cost. Moreover, rapid prototyping is cost and time effective when it can substitute handcrafting, CNC manufacturing, or silicon molding. The downside when compared to these methods is often poor surface quality and inferior dimensional accuracy. However, RP enables fast iterative testing of products with a low threshold of prototypes failing expectations. This makes it a superior tool in product development and explains why prototyping has been the leading application of AM. (Wohlers 2013)

Source: Anonymous. (2015). Bachelor Thesis. Adapted from Anonymous, Bachelor thesis, School of Engineering, Aalto University, Espoo Finland, 2015. This work is licensed under an Attribution-NonCommercialNoDerivatives 4.0 International license.

This style has several inherent problems. To begin with, it significantly limits the writer from utilising what the noted academic writing scholar Ken Hyland (2005) has called stance and engagement within the actual paragraph. This is where the writer adds their own authorial voice to the text by interacting with the source material and with the readership in order to situate themselves in their community of academic peers. This interaction is achieved in the context of stance and engagement by the use of attitudinal markers, boosting, hedging, self-mentioning, directives, personal asides, questions, reader pronouns, and shared knowledge (Hyland 2005, 177). Within this long form Finnish paraphrase, the stance and engagement can logically be attributed only to the original cited source, not the current writer summarising the ideas of the source, for there is no meaningful way to discern ownership of ideas beyond the citation attribution. In example 8 above, it is possible to identify at least 10 separate statements made in the paragraph. Some of these are representative of stance, including claims (e.g., ‘The downside when compared to these methods is. . .’ and ‘This makes it a superior tool. . . and explains why prototyping has been the leading application in AM’) and logical connections (‘Moreover’, and ‘However’). Moreover, there are clear attempts at engagement with asides (e.g., ‘as the names implies’) and creating interpersonal solidarity with experts in the field through boosting (e.g., ‘extremely’ and ‘superior’). While some of these may have been the thesis writer’s own arguments, it would, for the reader, appear that these have all been paraphrased from the source (Wohlers 2013). From a larger perspective, this Finnish paraphrase style tends to promote a less critical style of writing where writers tend to summarise the work of others and avoid critically discussing individual ideas from sources as they are introduced.

Similarly, this Finnish paraphrase style can lead fledgling writers quite easily into practices that constitute plagiarism. For instance, when students write their bachelor’s thesis, it can often take the form of a literature review. When the perceived goal is to

summarise others' ideas, it can readily lead to an overuse of this FPP style. According to the Chicago Manual of Style, this could constitute plagiarism: '(u)se that is not fair will not be excused by paraphrasing. Traditional copyright doctrine treats extensive paraphrase as merely disguised copying' (University of Chicago Press 2017, 212). It is similar to the problem of overuse of block quotes in the arts, humanities, and social sciences.

Worse yet, the logic of the FPP style has led some students to the practice of summarising two or more sources into a single paragraph with the citations provided only at the end of the paragraph. This would certainly constitute plagiarism as there is no meaningful way for the reader to discern which idea or argument belongs to which author. Unfortunately, this logical leap does not appear to be a rare occurrence. In a recent survey of 41 theses written in English at Aalto University between 2008 and 2018, 85% (35 samples) used the FPP style, while the multiple citation problem occurred in 41% (17 samples) (Forget and Paloposki 2019).

While it is generally better to introduce a citation and immediately contextualise it (i.e., integrate it into your argumentation; explain its significance; agree/disagree with it; or contrast it), it is possible to continue discussing a single source without using the same citation at the end of every sentence. For instance, the Publication Manual of the APA (APA 2018) recommends maintaining a clear progression of the topic at the start of the next sentence.

Example 9: APA-recommended method of paraphrasing same source across consecutive sentences

Chen and Liu (2004) studied the effect of aggregate size distributions and the volume fraction of aggregate on the fracture parameters of concretes with strength 50–89 MPa under three-point bending test. For this purpose three various maximum aggregate sizes of 10, 15 and 20 mm were employed.

Source: Rashad, A. and Seleem, H. (2014). A Study of High Strength Concrete with Moderate Cement Content Incorporating Limestone Powder. *Building Re-search Journal*, 61(1): 43–58. DOI <https://doi.org/10.2478/brj-2014-0004>. This work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivatives 3.0 International license.

In example 9, it is clear the Rashad and Seleem are still referring to Chen and Liu's article in the second sentence by starting with 'For this purpose. . . aggregate sizes. . .' Although one would suffice, both noun phrases are clearly connected by topical progression to the narrative of the first sentence.

References in the Vancouver (IEEE) style

The reference list below contains examples of scholarly articles [1, 2], a book [3], a chapter in a book with editors [4], a conference publication [5], a master's thesis [6], a doctoral dissertation [7], a standard [8] and a webpage [9]. Note that the IEEE style allows DOIs, but does not require them. For online references, you should specify the 'accessed date' if it is a webpage that might change. Scholarly articles and theses should not change, and thus the access date is not important for such references. Today,

some periodicals use article numbers [2] instead of ordinary page numbers [1]. Please see [10] for more details.

Referring to interviews or works of art seems very uncommon using the IEEE style and the guide [10] does not mention such references at all.
